SUMMARY OF RESEARCH EXPERIENCE:

During intercalated BSc, assisted in research into renal physiology with Dr Nashat, and research into cardiovascular-respiratory reflexes with Prof E Neil.

During Student elective in Papua New Guinea, undertook project on oral rehydration, funded by the MRC, supervised by Prof D Morley, Inst. of Child Health.

In Antarctica, collected bacteriological samples for PhD study. Personally phage-typed all samples at the National Staphylococcal Reference Laboratory, Colindale. Worked on development of new typing system in Aberdeen under Professor H Pennington, using Western Blotting of culture supernatants.

Several projects were undertaken as a higher trainee, some of which led to successful publications. These included some clinical studies and some basic research. The main long term (and still ongoing) work has been on serological markers of infection. This has been conducted jointly with Dr Peter Lambert at Aston University, and I was a joint author in four papers. With my move to Coventry, I transferred this work to the department of biological sciences at Warwick University where I supervised a PhD student, but further research is still being conducted at Aston University and the University of Birmingham; a patent has been taken out on a serological test directly derived from my initial work.

NOTES ON PHD THESIS:

Carriage and attempted eradication of *S aureus* from an isolated community in Antarctica

Many studies have succeeded in eradicating nasal carriage of *S aureus* in 100% of subjects, but whenever there has been adequate follow-up, a significant proportion were carrying again within weeks or months. If it is a new phage type, they have been cleared and reinfected, but if it is the same phage type, have they been cleared and reinfected from a contact or was the organism just suppressed? Only by taking swabs from all contacts is it possible to distinguish between the two. This is only feasible if the subjects are in isolation for a prolonged period.

Nasal, axillary and perineal swabs were taken at weekly intervals from all of the 28 men wintering at Halley base, Antarctica for the 40 weeks of isolation over the 1983 winter. Despite the application of topical Naseptin to all subjects, eight men consistently carried their own phage type throughout the study. Eradication seemed to be achieved in two, but after a long interval (39 weeks in one) their strain reappeared.

In an effort to find where the bacteria were persisting, throat swabs were taken. *S aureus* was found in the throats of nine of the twelve persistent carriers.

Two consistent and one intermittent carrier yielded non-typable strains. An alternative typing method was developed using PAGE (polyacrylamide gel electrophoresis) and immunoblotting of extracellular proteins. Other workers have shown interest in applying this technique to multiple resistant *S aureus* (MRSA), which does not phage type easily or reliably.

Conclusions:

1. Topical antibacterials are unlikely to eradicate *S aureus* from the nose, particularly in persistent carriers.
2. Apparent eradication may represent suppression.
3. The throat may be a significant carrier site.
4. Individuals' carrier status is stable over many months.
5. Immunoblotting may provide a new typing method.
